

A Great Paper on Testing Section Detection

Jane Doe, John Smith

Abstract

This paper studies a synthetic evaluation harness for section detection heuristics. We show that a demonstration of the merge algorithm correctly identifies numbered and keyword headings across a multi-page document, and we discuss limitations of the approach in detail. This filler abstract paragraph contains enough distinct words to keep the alphabetic ratio and character count comfortably above the extraction quality thresholds used elsewhere in the pipeline for testing purposes today and every day this week.

1 Introduction

This is the introduction section of the paper. It restates the abstract in more detail and motivates the reader with background on why section detection matters for retrieval augmented generation pipelines that operate over academic papers pulled from arXiv on a daily basis for busy engineers who need quick summaries of recent work without reading the full text themselves every single time.

2 Related Work

Prior work on this topic includes many heuristic approaches to layout analysis used to extract clean reading-order text from PDF documents that were typeset with complex multi-column layouts and figures interspersed throughout the main body of the document.

3 Method

Our method merges three signals: numbered headings, canonical keyword headings, and font-size based candidates gathered while extracting the document with PyMuPDF. We describe each step in turn below with sufficient detail for another engineer to reproduce our results independently on a different machine.

4 Experiments

We evaluate our approach on a synthetic multi-page fixture document constructed specifically for this unit test suite, comparing detected section boundaries against the ground truth boundaries we inserted ourselves while writing this generator script earlier this afternoon before running the full test suite.

5 Results

Results show that the merge algorithm recovers every inserted heading with high precision and recall on this synthetic fixture, though real papers will naturally be messier than this constructed example with irregular fonts and inconsistent heading numbering schemes across different subsections.

6 Conclusion

In conclusion, the section detection heuristics described above are sufficient for the purposes of this take home assessment project and its accompanying automated test suite, though we note several limitations that a production system would need to address before relying on this approach for real academic PDFs.
